Poor infection prevention and control standards are associated with environmental contamination with carbapenemase-producing *Enterobacterales* and other multidrug-resistant bacteria in Swiss companion animal clinics

Abstract

Intensive medical care of companion animals poses a risk for the selection and dissemination of multidrug-resistant organisms (MDROs). Infection prevention and control (IPC) concepts are essential to reduce the spread of MDROs, but data on IPC standards in companion animal clinics is sparse.

The study scored 34 areas of IPC in seven companion animal clinics and practices in Switzerland using structured IPC audits, and combined results with environmental MDRO contamination and MDRO carriage of the personnel. Environmental swabs, nasal and stool samples were tested for methicillin-resistant (MR) staphylococci and macrococci and for colistin-resistant, extended-spectrum β -lactamase- and carbapenemase-producing *Enterobacterales* (CPE).

Of a maximum IPC score of 68, the institutions reached a median (range) score of 33 (19–55). MDROs were detected in median (range) 8.2% (0–33.3%) of the sampling sites. Clinics with low IPC standards showed extensive contamination. CPE were detected in two clinics; one of them showed extensive contamination with CP *Klebsiella pneumoniae* (ST11, *bla*_{OXA-48}) and MR *Staphylococcus pseudintermedius* (ST551, *mecA*). Two employees carried CP *Escherichia coli* closely related to environmental (ST410, *bla*_{OXA-181}) and patient-derived isolates (ST167, *bla*_{NDM-5}).

IPC standards in companion animal clinics are variable and insufficient IPC standards can contribute to the evolution of MDROs which can be transferred between the environment and working personnel.

Poor infection prevention and control standards are associated with environmental contamination with carbapenemase-producing *Enterobacterales* and other multidrug-resistant bacteria in Swiss companion animal clinics

Zusammenfassung

Die intensivmedizinische Versorgung von Kleintieren stellt ein Risiko für die Selektion multiresistenter Organismen (MDROs) dar. Massnahmen in Infektionsprävention und -kontrolle (IPK) verhindern die Übertragung von MDROs, jedoch gibt es wenig Daten zur IPK in Kleintierkliniken.

In strukturierten Audits wurden 34 IPK Bereiche in sieben Schweizer Kleintierkliniken und -praxen beurteilt und die Ergebnisse mit der Häufigkeit von MDROs auf ‘High-touch’ Oberflächen (HTO) und beim Personal verglichen. Abstriche von HTO und Nasen- und Stuhlproben von Mitarbeitern wurden auf Methicillin-resistente (MR) Staphylokokken und Makrokokken, Colistin-resistente und Extended-Spektrum β -Laktamase- und Carbapenemase-produzierende *Enterobacterales* (CPE) untersucht.

Vom maximalen IPK Score (68) erreichten die Institutionen einen medianen Score von 33 (Range: 19–55). Im Median waren 8,2% (Range: 0–33,3%) der HTO MDRO-positiv.

Kliniken mit tiefen IPK Standards zeigten eine umfangreiche Kontamination. CPE wurden in zwei Kliniken nachgewiesen; eine Klinik war stark mit CP *Klebsiella pneumoniae* (ST11, *bla_{OXA-48}*) und MR *Staphylococcus pseudintermedius* (ST551, *mecA*) kontaminiert. Zwei Mitarbeiter trugen CP *Escherichia coli* (ST410, *bla_{OXA-181}*, ST167, *bla_{NDM-5}*), welche eng mit Isolaten der Umgebung bzw. von Patienten verwandt waren.

IPK Standards in Kleintierkliniken variieren stark und unzureichende Standards tragen zur Selektion von MDROs bei, die zwischen Umwelt und Personal zirkulieren können.

Abstract

Background. Intensive medical care in companion animal clinics could pose a risk for the selection and dissemination of multidrug-resistant organisms (MDROs). Infection prevention and control (IPC) concepts are key measures to reduce the spread of MDROs, but data on IPC standards in companion animal clinics is sparse. The study assessed IPC standards in seven companion animal clinics and practices in Switzerland by structured IPC audits and combined results with environmental MDRO contamination and MDRO carriage of the personnel.

Methods. IPC audits were held between August 2018 and January 2019. The observations in 34 IPC areas were scored based on predefined criteria (not fulfilled/partially fulfilled/fulfilled = score 0/1/2). Environmental swabs and nasal and stool samples from veterinary personnel were tested for methicillin-resistant (MR) staphylococci and macrococci and for colistin-resistant, extended-spectrum β -lactamase- and carbapenemase-producing (CP) *Enterobacterales* (CPE). Species was identified by MALDI-TOF MS, antimicrobial resistance determined by microdilution and β -lactam resistance gene detection, and genetic relatedness assessed by REP-/ERIC-PCR and multilocus sequence typing.

Results. Of a maximum total IPC score of 68, the institutions reached a median (range) score of 33 (19–55). MDROs were detected in median (range) 8.2% (0–33.3%) of the sampling sites. Clinics with low IPC standards showed extensive environmental contamination, i.e. of intensive care units, consultation rooms and utensils. CPE were detected in two clinics; one of them showed extensive contamination with CP *Klebsiella pneumoniae* (ST11, *bla*_{OXA-48}) and MR *Staphylococcus pseudintermedius* (ST551, *mecA*). Despite low IPC scores, environmental contamination with MDROs was low in primary opinion practices. Three employees were colonized with *Escherichia coli* ST131 (*bla*_{CTX-M-15}, *bla*_{CTX-M-27}, *bla*_{CTX-M-14}). Two employees carried CP *E. coli* closely related to environmental (ST410, *bla*_{OXA-181}) and patient-derived isolates (ST167, *bla*_{NDM-5}). MR *Staphylococcus aureus* (ST225, *mecA*) and MR *S. pseudintermedius* (ST551, *mecA*) of the same sequence types and with similar resistance profiles were found in employees and the environment in two clinics.

Conclusions. The study indicates that IPC standards in companion animal clinics are variable and that insufficient IPC standards could contribute to the evolution of MDROs which can be transferred between the environment and working personnel. The

implementation of IPC concepts in companion animal clinics should urgently be promoted.

Background

Antimicrobial resistance (AMR) is an increasing challenge in human and veterinary health care and an emerging threat for public health [1]. Because multidrug-resistant (MDR) organisms (MDROs) are exchanged between humans, animals and the environment, the combat of AMR needs to be done under a One Health approach [2]. In addition to antimicrobial misuse and overuse in human and veterinary medicine, health care-associated transmission is regarded as a third main driver in the development and spread of AMR [3]. Infection prevention and control (IPC) concepts are well established in human health care settings to reduce the risk of transmission and spread of MDROs [4].

Progress in the area of small animal intensive care has led to the establishment of large specialized clinics in industrial countries in Europe, the United States and Asia. In these settings, the development and transmission of MDROs is facilitated by: 1) the high density of patients susceptible for infections, 2) daily invasive health care interventions, 3) the high percentage of patients receiving antimicrobial therapy, and 4) the use of last-generation and highest priority critically important antimicrobials [5, 6]. Accordingly, outbreaks with methicillin-resistant (MR) *Staphylococcus aureus* (MRSA) and *Staphylococcus pseudintermedius* (MRSP) or highly resistant *Acinetobacter* spp. isolates in small animal clinics in Europe have been documented [7–10]. Most recently, an outbreak involving CP *Escherichia coli* was reported in a large companion animal clinic in Switzerland [11]. Because of the close contact of dogs and cats with their owners [12], the acquisition of MDROs by companion animals could pose a considerable risk to humans [13–15]. Zoonotic transmission of MDROs from pets to humans have been proposed for MRSA, MRSP, and extended-spectrum β -lactamase (ESBL) and carbapenemase-producing (CP)

Enterobacterales (CPE) [16–22]. Furthermore, MR coagulase-negative staphylococci (MRCoNS) with the same pulsed-field gel electrophoresis patterns were found in horses, personnel and environmental sites in an equine hospital in Denmark [23]. This finding suggests that MRCoNS strains can be shared between horses and personnel. MRCoNS represent an emerging cause of opportunistic infections in humans [24], and infections with MRCoNS have been documented in companion animals [25]. Recently, a novel *Macrococcus* spp., namely *Macrococcus canis*, has been isolated from healthy dogs and from infection sites of dogs; some isolates exhibited a MDR pattern [26, 27]. *M. canis* was found to have the ability to acquire AMR including methicillin resistance [28], but the potential contamination of the clinical environment with MR *Macrococcus* spp. has not yet been assessed.

Despite the key role of IPC concepts in limiting the dissemination of MDROs in human health care settings, data on IPC standards in companion animal veterinary institutions is sparse. The aim of the present prospective study was to evaluate IPC standards in different types of companion animal clinics and practices in Switzerland using structured IPC audits. Results were combined with investigations of the clinical environment and working staff for the presence or carriage of MR staphylococci, ESBL-producing, CP and colistin-resistant (COL-R) Enterobacterales and MR *Macrococcus* spp.

Methods

Aim, study design and IPC audits

The present prospective study was part of a large nation-wide project assessing the role of companion animal clinics in the dissemination of MDROs.

Three large clinics (A–C), two medium-sized clinics (D–E) and two first opinion practices (F–G) for companion animals were recruited. The institutions were chosen to be located in different parts of Switzerland and to cover different clinic/practice types (Additional file 1). One structured one-day audit per clinic or practice was performed between August 2018 and January 2019 by infectious disease specialists from human and small animal medicine to evaluate IPC standards. The audits covered 11 areas and 34 topics of IPC in small animal veterinary medicine [29, 30] and the observations were recorded and scored based on the criteria specified in Additional file 2. A score per IPC area and a total IPC score were calculated for each

companion animal clinic and practice. Participation in the study was voluntary and was not reimbursed. The participating clinics and practices received a written report of the audits with suggestions for areas of improvements.

Environmental sample collection

Samples from high-touch surfaces were collected in the institutions between June and November 2018. Sample collection was performed during a one-day visit from a list of high-touch surfaces (Additional file 3) including 69 sampling sites in large clinics (A–C) and 49 sampling sites in medium-sized clinics and practices (D–G). Differences in the number of resulting sampling sites at the different institutions were due to differences in infrastructure. The sampled surfaces were not disclosed prior to sampling. Samples were collected using transport swabs with enclosed tube containing Amies transport medium (Sarstedt AG & Co. KG, Nümbrecht, Germany). Environmental samples were tested for MRSA, MRSP, MRCoNS, MR *Macrococcus* spp., and ESBL-producing, CP and COL-R Enterobacterales (see below). In Clinic B, an additional 58 swabs were collected by the staff of the clinic in August 2018 from known high-risk areas (emergency room, n = 17; intensive care unit (ICU), n = 25; wards, n = 10; consultation room, n = 1; elevator, n = 1; lingerie, n = 2; entrance, n = 1; thermometers (10 pooled), n = 1) and analyzed specifically for CP Enterobacterales.

Sample collection from employees

Veterinary employees in Clinics A–C and Practice G were recruited for the study and instructed by an information session held at the according institution. Participating staff self-collected a stool and a mid-turbinate nasal sample using a sampling kit (swabs and transport tubes containing Amies transport medium, Sarstedt AG & Co. KG; stool sample collection kit, Novoglas Labortechnik Langenbrinck, Niederrohrdorf, Switzerland). The samples were put into a transport container and sent to the Institute for Infectious Diseases, University of Bern, Switzerland for analysis. Nasal swabs were analyzed for MRSA, MRSP and MRCoNS, and the stool samples for COL-R Enterobacterales, and ESBL-producing and CP Enterobacterales as described below. The participants filled a questionnaire to obtain data on age, sex, clinic/ practice type, working division and position, working duties, pet ownership, diet, medical history, medical and antibiotic treatment in the past, contact to the

human health care system and to MDRO-carriers, and leisure and travel activities in order to evaluate risk factors for MDRO carriage. The questionnaire was pre-labelled with the pseudonymization number.

Isolation and identification of the strains

MRSA, MRSP, MRCoNS and MR *Macrococcus* spp. were cultured using a two-step enrichment procedure and selected on chromogenic selective MRSA agar plates (BBL CHROMagar MRSA II, Becton Dickinson GmbH, Heidelberg, Germany) [31].

COL-R, 3rd generation cephalosporin-resistant and carbapenem-resistant Enterobacterales including *E. coli* and *Klebsiella* spp. were isolated after overnight enrichment in Luria-Bertani broth on specific selective plates including ChromID ESBL, ChromID CARBA SMART (bioMérieux, Suisse S.A., Geneva, Switzerland), and CHROMagar plates supplemented with Colistin (bio- Mérieux). Colonies were purified onto MacConkey II Agar (Becton Dickinson GmbH) and identified to the species level by matrix-assisted laser desorption/ ionization time-of-flight mass spectrometry (MALDI- TOF MS) analysis (Microflex LT, Bruker Daltonics GmbH, Bremen, Germany).

Antibiotic susceptibility testing and strain typing

Antimicrobial susceptibility was determined by the measurement of the minimal inhibitory concentrations (MICs) of different antibiotics by broth microdilution using Sensititre EUST, EUVSEC, EUVSEC2 and GNX2F plates (Thermo Fisher Scientific, Waltham, USA). For *Staphylococcus* and *Macrococcus* species, MICs of 18 antimicrobials as specified in Table 1 were determined. MIC results were interpreted using the European Committee on Antimicrobial Susceptibility Testing (EUCAST) criteria [32], except for kanamycin and sulfamethoxazole, for which the Clinical and Laboratory Standards Institute (CLSI) criteria were used [33]; no clinical breakpoints were available for streptomycin. For the Enterobacterales, MICs of 14 antimicrobials as specified in Table 2 were determined. MIC results were interpreted using the EUCAST criteria [32], except for nalidixic acid, sulfamethoxazole and tetracycline, for which criteria from the CLSI were used [33]; no clinical breakpoints were available for azithromycin. The methicillin resistance genes *mecA*, *mecB*, and *mecD* were identified by PCR as previously described [34–36]. The ESBL and carbapenemase genes were identified using the CT103XL microarray (Check-Points, Wageningen,

The Netherlands). Genetic relationships and clonality between isolates of the same species were determined by REP –/ERIC-PCR [37, 38] and by multilocus sequence typing (MLST) for MRSA, MRSP, MRCoNS, MR *Macrococcus* spp. using the corresponding schemes published in the PubMLST database (<https://pubmlst.org/databases/>) and for COL-R, ESBL-producing and CP Enterobacterales using the Center for Genomic Epidemiology (<http://www.genomicepidemiology.org/>).

Data analysis

Data from employees were collected and managed using REDCap (Research Electronic Data Capture) hosted at the University of Bern, Switzerland [39, 40]. Statistical analysis was performed using SPSS version 24.0.0. (IBM, Zurich, Switzerland) and the freely available software program R version 3.2.0 [41]. A total of 26 categorical parameters were statistically analyzed for association with carriage of Gram-positive or Gram-negative MDROs in employees using the Chi square and Fisher's exact test (for expected frequencies < 5). P-values < 0.05 were considered statistically significant.

Results

IPC audit scores

Five small animal clinics and two first opinion practices from Switzerland participated in the study (Additional file 1). Of a maximum total IPC score of 68, the clinics/practices reached a median (range) total IPC score of 33 (19–55) (Table 3). Major IPC deficits in the institutions were absence of written IPC manuals (4/7 institutions), absence of regular IPC audits (7/7 institutions), absence of written and updated protocols for cleaning and disinfection (4/7 institutions), absence of written protocols for quarantine measures (6/7 institutions) and no definition and flagging of patients with MDROs (5/7 institutions, Additional file 4).

Environmental contamination with MDROs

Results for environmental contamination with MDROs in the Clinics A–C and Clinics/Practices D–G are shown in Tables 4 and 5, respectively. Details on species, strains and antibiotic resistance profiles of the Gram-positive and Gram-negative isolates are given in Tables 1 and 2, respectively. Overall, MDROs were found in median (range) 8.2% (0–33.3%) of the environmental sampling sites in the seven

institutions; consultation rooms, ICUs and utensils were most commonly contaminated. In the additional samples collected in Clinic B, 22% tested positive for CP *K. pneumoniae* (ST11, bla_{OXA}-48, n =13); samples from the emergency room and ICU accounted for 12/13 positive samples. The results of the IPC scoring in the clinics were in accordance with the extent of environmental contamination. Clinics B, C and E with scores of 35, 33 and 19, respectively, showed most extensive environmental contamination, with 30, 32 and 33% of the sampling sites testing positive for MDROs, respectively (Tables 3, 4 and 5).

In Clinic B, the environment was highly contaminated with MRSP (ST551, mecA) and CP *K. pneumoniae* (ST11, bla_{OXA}-48); CP *E. coli* (ST410, bla_{OXA}-181; ST4038, bla_{OXA}-48) were found in single sampling sites (Tables 1 and 2). All 16 MRSP (ST551, mecA) isolates showed similar resistance profiles (Table 1). The total 18 CP *K. pneumoniae* (ST11, bla_{OXA}-48) isolates from the two sample collections in Clinic B also shared similar resistance profiles (Table 2) and showed the same REP-PCR profile (data not shown). In Clinic C, the environment was highly contaminated with MRCoNS (Table 1). Thirteen MR *Staphylococcus haemolyticus* isolates (ST9, mecA) were detected which showed similar resistance profiles (Table 1); 11 and 2S. *haemolyticus* isolates showed the same ERIC-PCR profiles, respectively (data not shown). In Clinic E, a diverse population of MDROs was found, predominated by MR *Micrococcus* spp. (ST69, mecB; ST71, mecB–D; ST35, ST38, ST72, mecD) and *S. haemolyticus* (ST30, ST42, ST69, mecA) isolates (Table 1); a single CP *E. coli* (bla_{OXA}-48) isolate was detected in a consultation room (Table 2). The MR *S. haemolyticus* isolates in Clinic E showed no clonal relationship in ERIC-PCR (data not shown) and different antibiotic resistance profiles (Table 1).

MDRO colonization of employees

A total of 109 employees of Clinics A–C and Practice G provided samples (99 nasal swabs and 108 fecal samples) and 108 employees completed the questionnaire. Results for MDRO carriage in employees are shown in Table 6, details on the detected Gram-positive and Gram-negative isolates are shown in Tables 1 and 2, respectively.

A total of 13 (13%) of the employees carried MR *Staphylococcus* spp., comprising 7 genetically diverse MRSA (ST398, ST7, ST45, ST97, ST5, ST225; *mecA*), one MRSP (ST551, *mecA*) and five MR *S. epidermidis* isolates. MR *Staphylococcus* spp. of the same sequence types and with similar AMR profiles were found in both employees and the environment in Clinic B (MRSP ST551) and Clinic C (MRSA ST225) (Table 1); no data on antibiotic resistance profiles and sequence typing were available for the MR *S. epidermidis* isolates. Carriage of MR *Staphylococcus* spp. was associated with the presence of an actual disease ($p = 0.036$) and contact to horses during work ($p = 0.049$). Actual diseases listed by employees with carriage of MR *Staphylococcus* spp. were: cystitis ($n = 1$), chronic sinusitis ($n = 2$) and Morbus Basedow ($n = 2$).

A total of 6 (6%) and 7 (7%) employees tested positive for ESBL-producing and COL-R Enterobacterales, respectively. There was no evidence for clonal relationship of these isolates based on sequence type, antibiotic resistance profiles (Table 2) and REP-PCR (data not shown). Three employees were colonized with *E. coli* ST131 (*bla*CTX-M-15, *bla*CTX-M-27, *bla*CTX-M-14, Table 2). Two staff members were found to be carriers of CP *E. coli*; details of these isolates have been published [42]. A staff member in Clinic A carried a CP *E. coli* (ST167, *bla*NDM-5, *bla*CMY-2, *bla*TEM-30). In Clinic B, a staff member showed fecal carriage of a CP *E. coli* (ST410, *bla*OXA-181, *bla*CMY-42) isolate that was closely related to an isolate from the environment [42]. A significant association of carriage of Gram-negative MDROs was found for living in an urban environment ($p = 0.026$) and lack of outdoor activities ($p = 0.017$).

Discussion

This study documents variable IPC standards in companion animal clinics and practices in Switzerland and extensive contamination with MDROs in institutions with low IPC standards. Worryingly, CP Enterobacterales were detected in the environment of two companion animal clinics, one of them showing extensive contamination with both CP *K. pneumoniae* (ST11, *bla*OXA-48, *bla*DHA-1) and MRSP (ST551, *mecA*). The results of the study suggest that insufficient IPC standards in companion animal clinics are associated with environmental contamination with MDROs and may increase the risk of potential transfer of MDR

bacteria between the clinical environment, patients and employees. In this context, two employees in this study were found to be colonized with CP E. coli closely related to environmental or patient-derived isolates [43], and two staff members carried MRSA and MRSP of the same sequence type as found in the environment in the according institution, respectively; some of these results have been published [11, 42]. CPE have been classified as an “urgent” public health threat by the US Centers for Disease Control and Prevention because nosocomial infections in humans have been associated with a case fatality rate of up to 50% [44, 45]. Carbapenems are used as a last-resort therapy for invasive Gram-negative infections in humans [46]. Although not licensed for use in animals, they have been reported to be used occasionally in dogs and cats [5]. Interestingly, carbapenems have never been used in patients of Clinic B, suggesting that the development and clonal spread of the CPE in the environment of this clinic was not driven by selection pressure exerted by carbapenems [11].

Several deficits in IPC could have contributed to the extensive spread of MRSP and CPE in Clinic B. The clinic had no written protocols on cleaning and disinfection in place. Disposable gloves were worn at every patient contact and routine hand disinfection was inconsistently performed. Utensils such as scissors or clippers were personalized to the staff members and carried in personal bum bags. This carries the risk of contamination of the utensils within the bags which could then act as vehicles to transfer MDROs between patients. In Switzerland, like in many other European countries, no legislation regulates the IPC standards in small animal veterinary clinics and practices. Furthermore, education of veterinary students and practicing veterinarians in IPC is hampered by a lack of IPC specialists and training programs in companion animal medicine [47]. Immediately after the discovery of the outbreak in Clinic B, a comprehensive IPC concept was implemented with the support of IPC professionals, hand disinfection dispensers were placed throughout the clinic and hand hygiene training has been initiated for all employees.

Overall, the IPC standards found in the companion animal clinics in Switzerland were variable. The deficits in IPC were illustrated by i.e. the absence of written IPC manuals in 4/7 institutions, no staff education on any IPC-related topics in 3/7 institutions, no definition and flagging of MDRO patients in 5/7 institutions, and no

written and updated protocols on quarantine measures in 6/7 institutions. Clinic E with the lowest total IPC score had no IPC management in place at all, no hand sanitizers and dispensers were available throughout the clinic and no guidelines for the handling of patients with MDROs were established.

Antimicrobial use is thought to be a major driving force towards antimicrobial resistance [3]. The IPC audits in this study assessed whether specified guidelines on the use and dosing of antimicrobials were available for all employees involved in prescription and application of antimicrobials, and whether use of antibiotics of last resort were restricted and limitations communicated and known to all employees; these aspects were completely fulfilled by 4/7 and 3/7 institutions, respectively. However, overall consumption of antimicrobials was not assessed because this data was not collected and monitored by the investigated institutions. An information system for antimicrobials (IS ABV) to monitor their consumption in all veterinary clinics and practices in Switzerland was introduced by the Swiss Federal Food Safety and Veterinary Office in October 2019 [48], after conclusion of this study, but reliable data from the system is not yet available.

Four institutions (A–D) included in the present study were recently evaluated for antimicrobial prescription habits in dogs and cats in two unrelated studies [49, 50]. In these investigations, the frequency of prescription and adherence to prudent use guidelines for three disease complexes in cats and four disease complexes in dogs were evaluated between January and December 2016. There was no difference in overall prescription rate among Clinics A–D for the evaluated cases (247 feline and 431 canine cases; BW and SS, personal communication). We therefore assume that overall antibiotic use was not a major contributor to the differences in environmental contamination with MDROs observed in Clinics A–D.

Whether the extensive environmental contamination poses a nosocomial infection risk for the patients in these institutions cannot be answered from this study. None of the evaluated institutions had an active surveillance of health care-associated infections in place. However, retrospective investigations to assess the role of CPE in nosocomial infections in Clinic B are underway.

Areas with high patient traffic, such as consultation rooms and ICUs, and utensils were most commonly contaminated with MDROs. High rates of contamination with MR staphylococci in high traffic areas within a veterinary hospital have been documented [51]. The clonal relationship of the MDROs in the environment of Clinics B and C also suggests a spread from a common source in these institutions. Practices F and G on the other hand reached rather low IPC scores in fact, however, environmental contamination was low in both practices. This could indicate that first opinion practices in contrast to large referral clinics are less critical in the development and spread of MDROs. Studies in human medicine suggest that the influx of resistant pathogens varies significantly in hospitals of different size, location and patient groups [52]. Therefore, a large clinic could be at higher risk for the introduction of MDR pathogens than first opinion practices [2]. Since the number of first opinion practices included in this study was low, no conclusions can yet be drawn and future studies should address the role of first opinion practices in the development and spread of MDROs.

The prevalence of colonization with ESBL-producing or COL-R Enterobacterales in veterinary employees in this study was comparable to the colonization rate in the general population in Switzerland [53, 54]. Three employees from Clinics A and B were found to be colonized with *E. coli* ST131 (blaCTX-M-15, blaCTX-M-27, blaCTX-M-14). *E. coli* ST131 is one of the most important globally disseminated bacterial lineage and causes severe hospital-acquired and community-onset MDR infections in humans [55]. Infections with *E. coli* ST131 have, amongst others, also been reported in companion animals [56]. Of note, an unrelated study investigated clinical samples originating from canine and feline patients from Clinic A and found that the prevalence of ESBL-producing uropathogenic *E. coli* ST131 had increased between 2010 and 2012 from 0 to 1.5%, and included *E. coli* ST131 (blaCTX-M-15 and blaCTX-M-27) [57].

The prevalence of colonization with MRSA in veterinary employees in this study was higher than reported for the general population in Switzerland (7% vs 1.5%) [58]. Variable MRSA sequence types were detected in the employees, including healthcare-associated (ST225, ST5, ST45, ST7), livestock-associated (ST398) and community-acquired MRSA (ST97). Veterinarians have an occupational risk for

acquisition of MRSA [59]. Contact with horses has been reported to be a risk factor for acquiring MRSA ST398 [60] and was also found to be associated with colonization with MR staphylococci in this study. Carriage of MRSP has been well documented in veterinarians and owners with contact to MRSP infected animals [16, 17, 21, 61, 62]. MRSP ST551 has so far only occasionally been reported in companion animals in Europe, but was found to have become the dominating MRSP lineage in dogs in Poland, but emerged not before 2015 [63]. An occupational acquisition of MRSP ST551 by the employee in Clinic B due to extensive environmental contamination with this clone seems most likely.

Environmental detection of macrococci was common in this study, especially in Clinic E. The identified sequence types were highly variable, which was recently also found for macrococci isolated from carriage and infection sites of dogs [27]. The macrococci sequence types found in the environment did not match the lineages recently documented in dogs in Switzerland [27]. The clinical significance of macrococci in companion animals and the impact of environmental contamination with macrococci has not yet been resolved and needs further investigations.

Conclusions

The present study documents variable IPC standards in companion animal clinics and practices in Switzerland. Low IPC standards in clinics were associated with extensive environmental MDRO contamination. The detection of an MRSP and CP Enterobacterales outbreak in one clinic and of closely related MDRO isolates in employees, patients and the environment in several clinics indicate that insufficient IPC standards in companion animal clinics may pose a public health risk. The results suggest that companion animal clinics can significantly contribute to the development and dissemination of MDROs. Proper IPC standards in small animal veterinary clinics and educational programs in IPC for veterinary students and practitioners should therefore urgently be promoted.

Infection prevention and control; ICU: Intensive care unit; MALDI-TOF MS: Matrix-Assisted-Laser-Desorption/Ionization-Time-Of-Flight- Mass-Spectrometry; MR: Methicillin-resistant; MRCoNS: Methicillin-resistant coagulase-negative staphylococci; MRSA: Methicillin-resistant *Staphylococcus aureus*; MRSP: Methicillin-resistant *Staphylococcus pseudintermedius*; MICs: Minimal inhibitory concentrations; MDR: Multidrug-resistant; MDROs: Multidrug-resistant organisms

Declarations

Acknowledgements

We thank Alexandra Collaud, Institute of Veterinary Bacteriology, University of Bern, for technical assistance, and Alina Hubbuch, Claudia Lehner and Kira Schmitt for summarizing the data on antimicrobial prescriptions in Clinics A– D. We are grateful to all clinics, practices and employees who participated in the study.

Authors' contributions

BW, SPK, SS, SGB, VP and EA conceived the study. BW and SS were responsible for the coordination of the study, and VP, SGB and EA supervised and coordinated the bacteriological and molecular analyses. JSS, SPK, SS and BW participated in the IPC audits, and JSS, SPK and BW did the audit scoring. JSS, VD, HR and AN were responsible for the sample and data collection. AN, MB, OJB, TB and EIC performed the bacteriological and molecular analyses. BW and JSS drafted the manuscript. BW, JSS, SPK, VP, SS, MB, SGB and EA edited the manuscript. All authors read and approved the final manuscript.

Funding

The study was supported by the Swiss Federal Food Safety and Veterinary Office (Grant No. 1.18.10 to BW, SS, SPK, AE, VP and SGB), the Swiss National Science Foundation (NRP-72, “National Research Program, Antimicrobial Resistance”; SNF grant No. 177378 to AE and VP), and by internal funds of the Institute of Veterinary Bacteriology, University of Bern. The funding body had no role in the design of the study and collection, analysis, and interpretation of data and in writing the manuscript.

Availability of data and materials

Thirteen whole genome sequences have been deposited on BioProject

PRJNA587632 in GenBank. The datasets used and analyzed during this study are available from the corresponding author on reasonable request.

Ethics approval and consent to participate

The research was conducted in accordance with the Declaration of Helsinki and national standards. The study protocol was approved by the ethics committee of the Canton of Berne, Switzerland (KEK-BE Nr.: 2018–00866). Written informed consent to participate was obtained from all participants.

Consent for publication

Written informed consent for publication was obtained from all participants.

Competing interests

The authors declare that they have no competing interests.

¹For the five *S. epidermidis* isolates from employees, no data on antibiotic resistance profile or strain typing was available. ²Sequence types of the coagulase-negative staphylococci were determined for the representative strains. ³MIC in bold indicates resistance. The resistance breakpoints presented are those for *Staphylococcus* spp. from the European Committee on Antimicrobial Susceptibility Testing (32) except for KAN and SMX for which the breakpoints from the Clinical and Laboratory Standards Institute (33) were used. ⁴No breakpoint was available for STR; an MIC > 32 was tentatively used as resistance breakpoint. ⁵EUCAST breakpoints for vancomycin: for *S. aureus* > 2, for coagulase-negative staphylococci > 4. *Abbreviations:* Env, environment; Empl, employee; ST, sequence type; CLI, clindamycin; TET, tetracycline; RIF, rifampicin; STR, streptomycin; FUS, fusidic acid; PEN, penicillin; CHL, chloramphenicol; KAN, kanamycin; SYN, synergid; VAN, vancomycin; GEN, gentamicin; TMP, trimethoprim; ERY, erythromycin; CIP, ciprofloxacin; FOX, ceftiofur; LZD, linezolid; MUP, mupirocin; SMX, sulfamethoxazole; S., *Staphylococcus*; M., *Micrococcus*.

Table 2. Characteristics and antibiotic resistance profile of the Gram–negative multidrug-resistant organisms.

Additional file 2. Criteria used for infection prevention and control (IPC) scoring in the seven companion animal institutions and as evaluated during one-day IPC audits. Each IPC topic was scored as follows: all criteria fulfilled= score 2; part of the criteria fulfilled= score 1; no criteria fulfilled= score 0. A score per IPC area and a total score was calculated. The results of the IPC scoring of the participating institutions are given in Table 3 and Additional file 4.

IPC area	IPC topic	Criteria for assessment
IPC management	Hygiene manual	Written IPC manual containing the relevant areas of IPC and provided in written/online form to all employees
	Designated IPC team/person	A defined person or group of people (in large clinics) responsible for IPC implementation, control and teaching that has the according knowledge; in case of IPC groups: regular meetings take place
	Regular audits	IPC audits in the clinic/practice by the IPC mandatory/team or an external IPC advisor, taking place on a regular base
Staff education	Hand hygiene	Education in hand hygiene for all employees involved in clinical service, hold on a regular base
	General IPC	Education in infection prevention and control for all employees involved in clinical service, hold on a regular base
	Antimicrobial stewardship	Education in antimicrobial stewardship for all employees involved in prescription and application of antimicrobials, hold on a regular base
Cleaning/disinfection	Written & updated protocols	Disinfection protocols with type of disinfection, concentrations and residence times defined for different areas/equipment; written checklists to confirm regular cleaning/disinfection in different areas
	Spectrum and application	Licensed disinfection compounds for clinical use with sufficient bactericidal and virucidal spectrum and use in accordance with the manufacturer's instructions; cleaning procedures that allow for removal of organic matter and proper disinfection
	Information dissemination	Written protocols in all areas and available to all people involved in cleaning/disinfection
Isolation measures	Structure and work-flow	<u>For clinics:</u> patients with potential contagious diseases physically separated from other patients; isolation ward that allows for adequate patient separation that contains an upstream area with provision of hand sanitizer and protective clothing; utensils and equipment are assigned to each patient and remain in the isolation area until final cleaning/disinfection; no additional material stored within the isolation room

		<u>For practices:</u> potentially contagious ambulatory patients are summoned after other consultations; patient movement in the practice is restricted
	Information dissemination	Diseases requiring specific isolation/protective measures are specified and the information is available in written form to all employees
	Cleaning / disinfection	Disinfectants also covering parvovirus and fungal spores are used in the isolation areas; cleaning/disinfection procedures are defined and available to all employees
Guidelines for patients with MDROs	Definition/designation of MDRO patients	MDROs are defined and patients with MDRO infections are designated
	Protective measures	MDRO-infected patients are physically separated from other patients, patient movement in the institution is restricted, disinfection procedures are defined
Hand hygiene	Hand sanitizer	Hand sanitizer in single-use containers and dispensers are available at all hand washing stations; hand washing stations in all consultation and treatment rooms, wards, laboratories and toilets
	Washing lotion	Medical hand washing lotion in single-use containers available at all hand washing stations (see above)
	Skin protection products	Presence of skin care products available at all hand washing stations (see above)
	Disposable towels	Use of single-use disposable towels at all hand washing stations (see above)
Personal hygiene	Working clothes	Provision of working clothes (trousers, and top or coat) for all employees
	Hand jewelry and nails	No hand jewelry (watches, rings, bracelets or similar) and no long or artificial nails and nail polish allowed for employees involved in clinical work
	Food consumption	No consumption of food by employees in the patient areas
	Food storage	No food of employees stored within the patient areas/refrigerators
	Personnel changing rooms	Changing rooms available for all employees that allow to separate private and working clothes
	Laundry	Daily change of working clothes specified; working clothes are cleaned by an external company or by an in-house washing machine in the clinic
Protection of employees	Vaccinations	Tetanus and rabies vaccination recommended for all employees and costs covered by the clinic/practice

	Measures for pregnant/immunosuppressed employees	Protective measures in case of pregnancy and/or immunosuppression defined and communicated to all employees
Protective clothing	Composition	Complete protective equipment including disposable protective coats or overalls, gloves and shoe covers
	Use	Situation requiring protective clothing and correct use of protective clothing specified and information provided in written form to all employees involved in clinical work
	Storage and provision	<u>Clinics</u> : Protective clothing provided in front of the isolation area and with low potential for contamination of the equipment; <u>Practices</u> : stored with low potential for contamination
Medication	Preparation	Preparation of medication on a clean and disinfected working area; avoidance of preparation of medication beforehand
	Storage	Storage according to official regulations (e.g. temperature, storage time); in a clean area/fridge; with no contact to food, feed or patient samples
	Dating of open vials	Dating of open vials and consistently done for all medications
Guidelines and restrictions for antimicrobial use	Guidelines for antimicrobial use and dosing	Specified guidelines on use and dosing of antimicrobials available for all employees involved in prescription and application of antimicrobials
	Restrictions for critically important antimicrobials	Limited or prohibited use of antibiotics of last resort, restrictions are communicated and known to all employees

Abbreviations: IPC, Infection prevention and control; MDROs, multidrug resistant organisms.

Total score		55	35	33	48	19	33	20	243	476

Abbreviations: IPC, Infection prevention and control; MDROs, multidrug resistant organisms.

Acknowledgements

I am deeply indebted to PD Dr. Barbara Willi for her support, mentoring, and excellent guidance over the course of this project. I also thank PD Dr. Stefan Kuster for providing great advice and very helpful support and assistance.

Many colleagues at the University of Bern put an incredible amount of effort into measuring and processing countless bacteriological samples. This work would not have been possible without their commitment.

My special thanks go to all the clinics and practices and their staff who participated in this project and made it possible in the first place.

Last but by no means least, I would like to thank my family, especially my sister, for their warmest support.

Curriculum Vitae

Vorname Name	Janne Sophie Schmidt
Geburtsdatum	04.06.1990
Geburtsort	Hannover, Deutschland
Nationalität	deutsch
08/1996 – 07/2000	Grundschule St. Bernward-Schule Hannover, Deutschland
09/2000 – 07/2002	Ludwig-Windthorst-Schule Hannover, Deutschland
09/2002 – 06/2009	Gymnasium St. Ursula-Schule Hannover, Deutschland
23.06.2009	Allgemeine Hochschulreife (Abitur) an der St. Ursula-Schule in Hannover, Deutschland
10/2009 – 03/2010	Studium der Humanmedizin an der Medizinischen Hochschule Hannover, Deutschland
10/2010 – 05/2018	Studium der Veterinärmedizin an der Tierärztlichen Hochschule Hannover, Deutschland
05/2018	Abschlussprüfung vet. med. im Mai 2018 an der Tierärztlichen Hochschule Hannover, Deutschland
05/2018 – 05/2020	Anfertigung der Dissertation unter Leitung von PD Dr. med. vet. Barbara Willi am Departement für Kleintiere, Klinik für Kleintiermedizin, Vetsuisse-Fakultät Universität Zürich Vorsteher: Prof. Dr. med. vet. Antonio Pozzi
09/2019 –	Internship in der Tierklinik Aarau West AG, Oberentfelden, Schweiz
